- Higgs mechanism
- Higgs production mechanisms and decays

2 LHC and CMS

- LHC
- CMS detector

3 Event selection and reconstruction

- Topology of tH
- Main backgrounds
- Event selection
- BDT
- Previous results
- Systematic uncertainties

4 Statistical analysis

- Likelihood model
- Results

5 Results

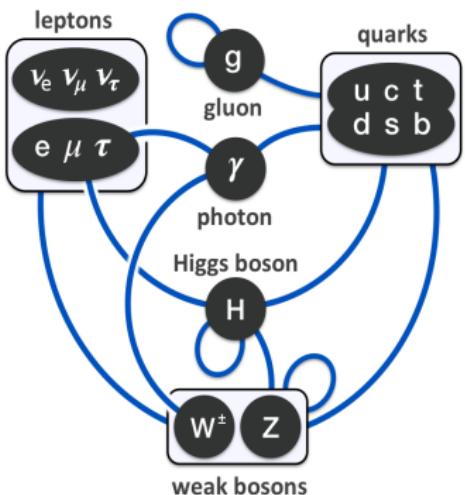

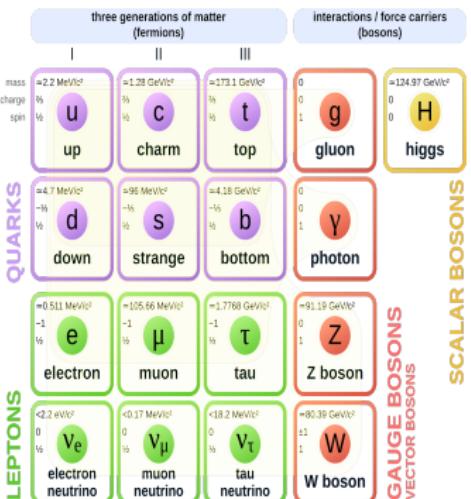

Motivation for single top Higgs (tH)

- Coupling measurement is essential to establish the nature of the Higgs
- The exploration of Higgs production on the tH channel is subject relatively new. Measurements of CMS and ATLAS are compatible with SM predictions.
- The tH study explores the relative sign of top-Higgs and W-Higgs couplings.
Small deviations from SM predictions could be associated with physics beyond the standard model (BSM) such as Supersymmetry.

Standard Model

Standard Model of Elementary Particles

Particles Properties

Table of particles in SM

Particle	Mass (MeV/ c^2)	Charge	spin	Lifetime (s)	Distance in lifetime (meters)
Up (u)	2.2	$\frac{2}{3}$	$\frac{1}{2}$	stable	-
Charm (c)	1280	$\frac{2}{3}$	$\frac{1}{2}$	1.1×10^{-12}	5.21×10^{-3}
Top (t)	173100	$\frac{2}{3}$	$\frac{1}{2}$	5×10^{-25}	2.37×10^{-15}
Down (d)	4.6	$-\frac{1}{3}$	$\frac{1}{2}$	Stable	-
Strange (s)	96	$-\frac{1}{3}$	$\frac{1}{2}$	1.24×10^{-8}	58.7
Bottom (b)	4180	$-\frac{1}{3}$	$\frac{1}{2}$	1.3×10^{-12}	6.16×10^{-3}
W	80379	± 1	1	3×10^{-25}	1.42×10^{-15}
Z	91187.6	0	1	3×10^{-25}	1.42×10^{-15}
Photon (γ)	0	0	1	Stable	-
Gluon (g)	0	0	1	Stable	-
Higgs (H)	125.18	0	0	1.56×10^{-22}	7.39×10^{-13}
Electron (e)	0.511	-1	$\frac{1}{2}$	Stable	-
Muon (μ)	105.7	-1	$\frac{1}{2}$	2.2×10^{-6}	10419.85
τ	1776.86	-1	$\frac{1}{2}$	2.9×10^{-13}	1.37×10^{-3}
$\nu_e \nu_\mu \nu_\tau$	0	0	$\frac{1}{2}$	Stable	-

Stable means no decay, or lifetime almost infinite. Particles speeds at 0.998c

Electroweak SM Lagrangian

Higgs lagrangian

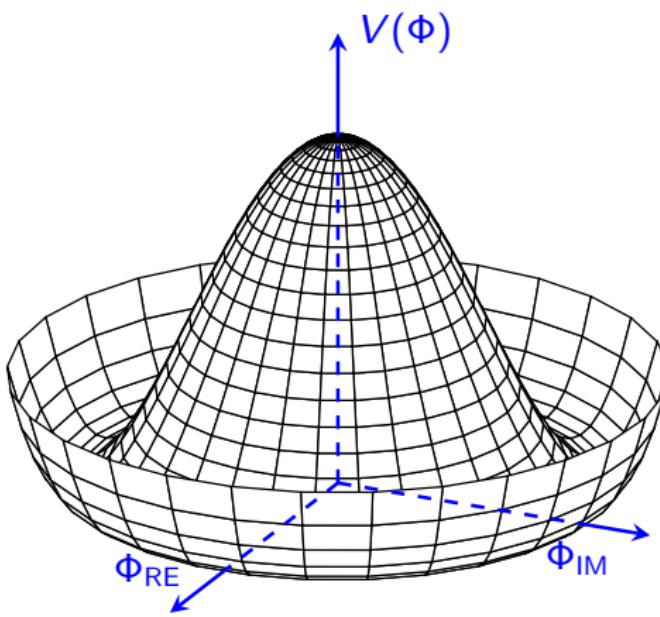

$$\mathcal{L}_{\text{Higgs}} = (D_\mu \Phi)^\dagger (D^\mu \Phi) - V(\Phi^\dagger \Phi) \quad (1)$$

with

- $D_\mu \Phi = \left(\partial_\mu + (ig/2)\sigma^i W_\mu^i - i\frac{1}{2}g' B_\mu \right) \Phi$
- $V(\Phi^\dagger \Phi) = -\mu^2 \Phi^\dagger \Phi + \frac{1}{2}\lambda(\Phi^\dagger \Phi)^2, \quad \mu^2 > 0$
- $\Phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$ is a SU(2) doublet.
- σ^i are the Pauli matrices.
- Φ is higgs field which is a complex scalar field. Φ
- λ and μ^2 are Higgs potential parameters

Electroweak SM Lagrangian

Higgs potential $V(\Phi^\dagger \Phi)$ for $\mu^2 < 0$ and $\lambda > 0$, also called the mexican hat potential.

SM Lagrangian

Yukawa lagrangian

$$\mathcal{L}_{\text{yukawa}} = \sum_{m,n}^3 \Gamma_{mn}^u \bar{q}_{m,L} \tilde{\Phi} u_{n,R} \quad (2)$$

where h.c is hermitian conjugate. m and n are flavors of quarks and leptons.

The matrices Γ_{mn} describe the so called Yukawa couplings between higgs doublet ϕ and the fermions.

Choosing

$$\Phi = -\frac{1}{2} \begin{pmatrix} 0 \\ v + h \end{pmatrix}$$

By using 3 it on $\mathcal{L}_{\text{yukawa}}$, it is obtained for u quark

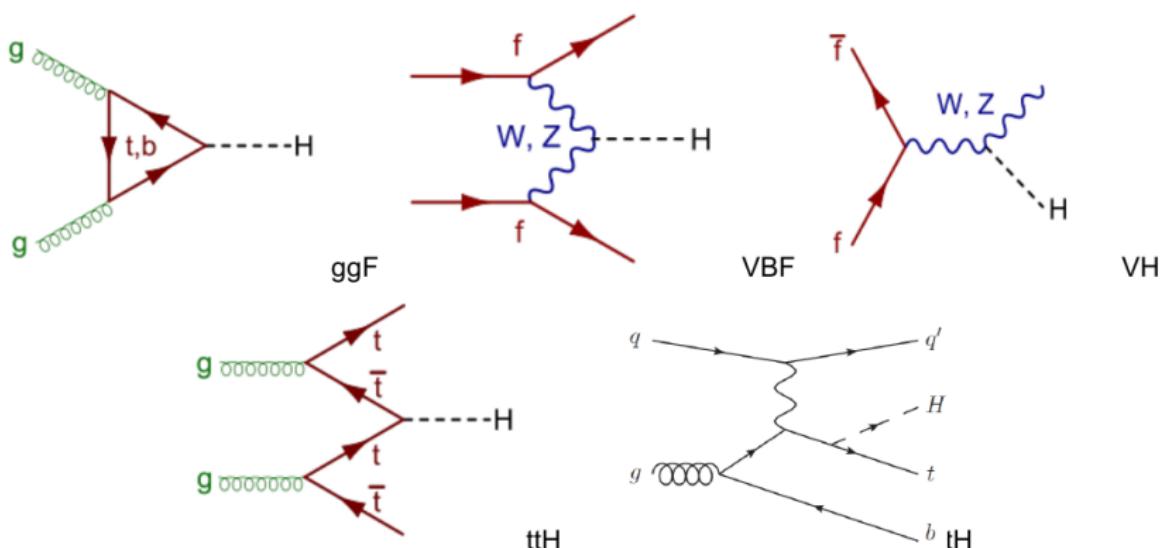

$$\frac{\Gamma_{uu}^u v}{\sqrt{2}} (\bar{u}_L u_R + \bar{u}_R u_L)$$

from which the masses for the fermions shown to be proportional to the Yukawa couplings

$$m_u = -\frac{\Gamma_{uu}^u v}{\sqrt{2}}$$

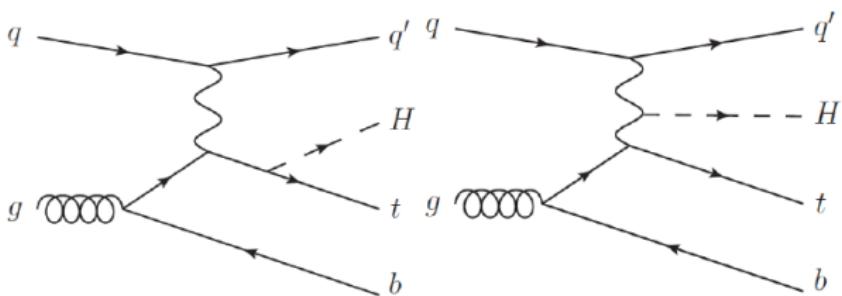

Higgs production mechanisms

Different Higgs production mechanism, from the most likely to least likely

tH production mechanisms

tH mechanism. Higgs radiated from a top quark (left). Higgs radiated from a W boson (right)

tH production mechanisms

- In a proton proton collision, the production cross section of the single top plus Higgs boson process is driven by a destructive interference of two main diagrams, where the Higgs couples to either the W boson or the top quark.
- A second process, where the Higgs and top quark are accompanied by a W boson (tHW) has similar behavior, albeit with a weaker interference pattern.
- However, in the presence of new physics, there may be relative opposite signs between the tH and WH couplings which lead to constructive interference and enhance the cross sections by an order of magnitude or more.

Cross section

- Cross section describes the likelihood of two particles interacting under certain conditions[1][8]
- Experimentally

$$d\sigma = \frac{\text{number of particles scattered into solid angle } \Delta\Omega}{(\text{number of particles incident})(\text{scattering centers/area})} \quad (3)$$

- Cross sections are expressed in barns , where $1 \text{ barn} = 10^{-34} \text{ cm}^{-2}$
- The reaction rate N_R is determined by the total cross section σ and the incident flux L .
 L is called luminosity and it is measured in $\text{cm}^{-1}\text{s}^{-1}$.[8]

$$N_R = \sigma L$$

(4)

Higgs production Cross section

Higgs boson production cross sections in pp collisions for $\sqrt{s} = 13\text{TeV}$ (in pico barn). Integrated luminosity of 35.9 fb^{-1} for Run 2¹

Branching ratio

In particle physics, the branching ratio for a decay process is the ratio of the number of particles which decay via a specific decay mode with respect to the total number of particles which decay via all decay modes.
².

$$\text{BR} = \frac{\Gamma_i}{\sum_i \Gamma_i} \quad (5)$$

Where $\Gamma = \sum_i \Gamma_i$ is the total decay width (sum of all partial widths) of the particle and is related to lifetime of the particle: $\Gamma = 1/\tau$. Since the dimension of Γ is the inverse of time, in our system of natural units, it is measured in inverse seconds.⁰

⁰ Cleaves H.J. (2011) Branching Ratio. In: Gargaud M. et al. (eds) Encyclopedia of Astrobiology. Springer, Berlin, Heidelberg

Higgs Branching ratios per channel

SM Higgs boson branching ratios for $M_H = 125$ GeV

Higgs decay	Branching ratio (BR)
$H \rightarrow b\bar{b}$	50.82%
$H \rightarrow W^+W^-$	21.5%
$H \rightarrow \tau^+\tau^-$	6.27%
$H \rightarrow ZZ$	2.61%
$H \rightarrow \gamma\gamma$	0.227%
$H \rightarrow Z\gamma$	0.153%
$H \rightarrow \mu^+\mu^-$	0.0217%

$\mu\mu$ same sign decay rate

Topology of events tH

The characteristics of the signal tH :

- $t \rightarrow W^+ b \rightarrow l^+ \nu_\mu b$
- $H \rightarrow W^+ W^-$
 - $W \rightarrow l^\pm \nu$, where l can be μ^\pm, e^\pm, τ^\pm
 - $W \rightarrow q\bar{q}$
 - W bosons decay leptonically resulting in a signature of two same-sign leptons
- a light-flavor quark
- A b-jet

Main backgrounds

Main backgrounds and their same sign $\mu\mu$ decay process

Background	Decay process

tZW^+	$tZW^+ \rightarrow W^+ b \mu^+ \mu^- \mu^+ \nu_\mu \rightarrow \mu^+ \nu_\mu b \mu^+ \mu^- \mu^+ \nu_\mu$
ZZ	$ZZ \rightarrow \mu^+ \mu^- \mu^+ \mu^-$
$t\bar{t}H$	$t\bar{t}H \rightarrow W^+ b W^- \bar{b} W^+ W^- \rightarrow \mu^+ \nu_\mu b \mu^- \bar{\nu}_\mu \bar{b} \mu^+ \nu_\mu \mu^- \bar{\nu}_\mu$

Event selection

In order to detect signal events and reject background, the following selections are applied.

- The events must contain two muons with the same sign.
- Transverse moment $p_t > 25$ GeV for the highest p_t muon and $p_t > 15$ GeV for the lowest p_t muon.
- A forward jet with $p_t > 40$ GeV and $|\eta| > 2.4$
- One or more b-tagged jets with $|\eta| < 2.4$

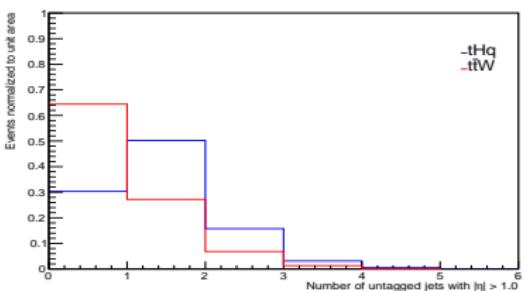

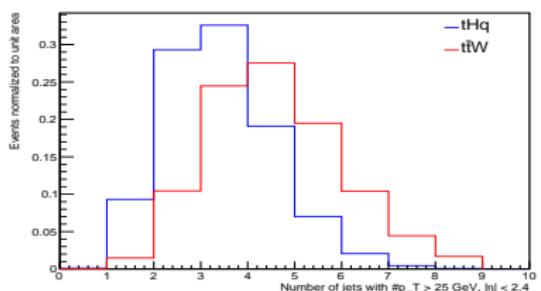

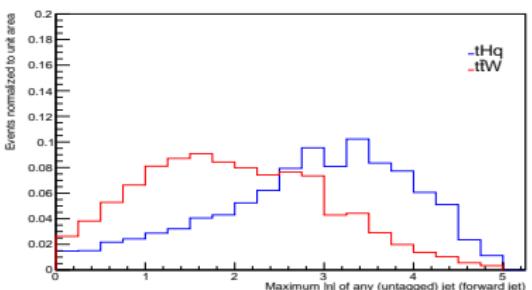

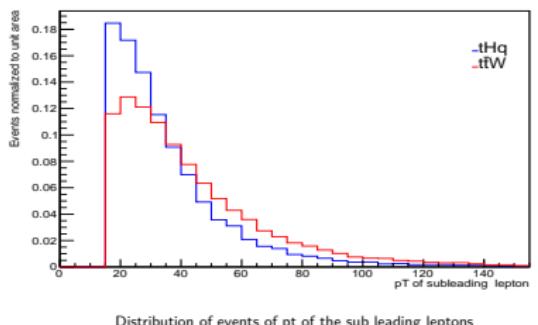

BDT

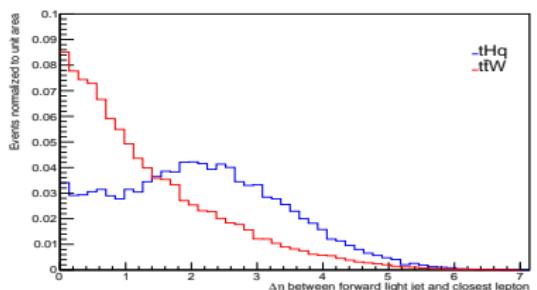

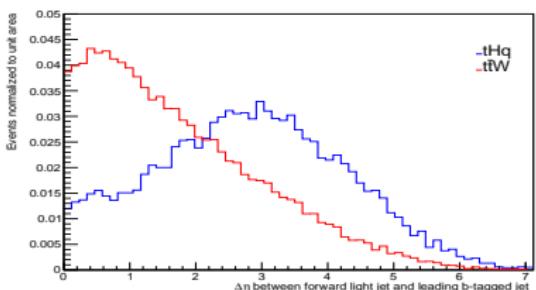

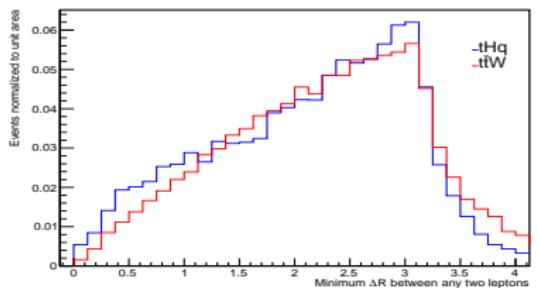

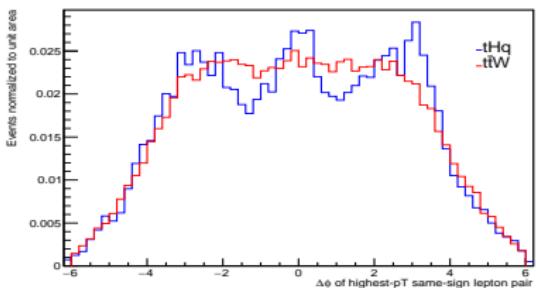

A decision tree takes a set of input features and splits input data recursively based on those features. Boosting is a method of combining many weak learners (trees) into a strong classifier. The features can be a mix of categorical and continuous data.

BDT Variables

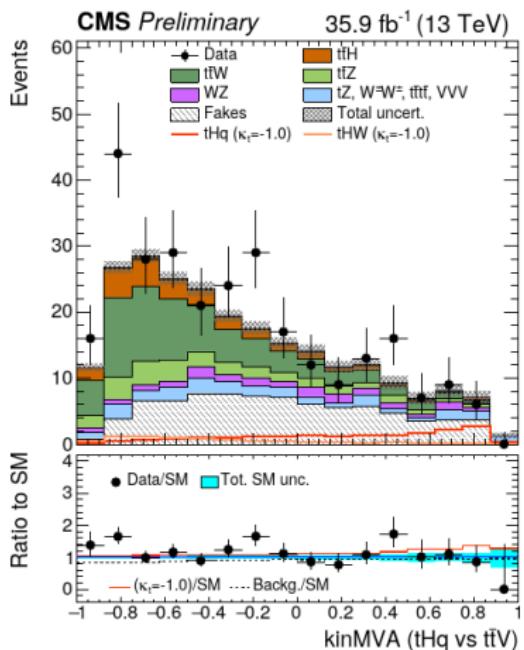

- Trailing lepton p_t
- Total charge of tight leptons
- $\min \Delta R$ (lepton pairs)
- $\Delta\phi$ between highest p_t lepton pair
- Number of jets with $|\eta| < 2.4$
- Number of non b-tagged jets with $|\eta| > 1.0$
- Maximum $|\eta|$ for jets
- $\Delta\eta$ (most forward light jet, closest lepton)
- $\Delta\eta$ (most forward light jet, hardest loosely b-tagged jet)
- $\Delta\eta$ (most forward light jet, 2nd hardest loosely b-tagged jet)

Distribution of events of $|\Delta\eta|$ between a forward jet and the closest leptonDistribution of events as function of $|\Delta\eta|$ between a forward jet and a b-tagged jetDistribution of events with a ΔR between the lepton pairs (highest and lowest pt)Distribution of events of $\Delta\phi$ between the higher pt pair of leptons

Distribution of events in the BDT discriminant

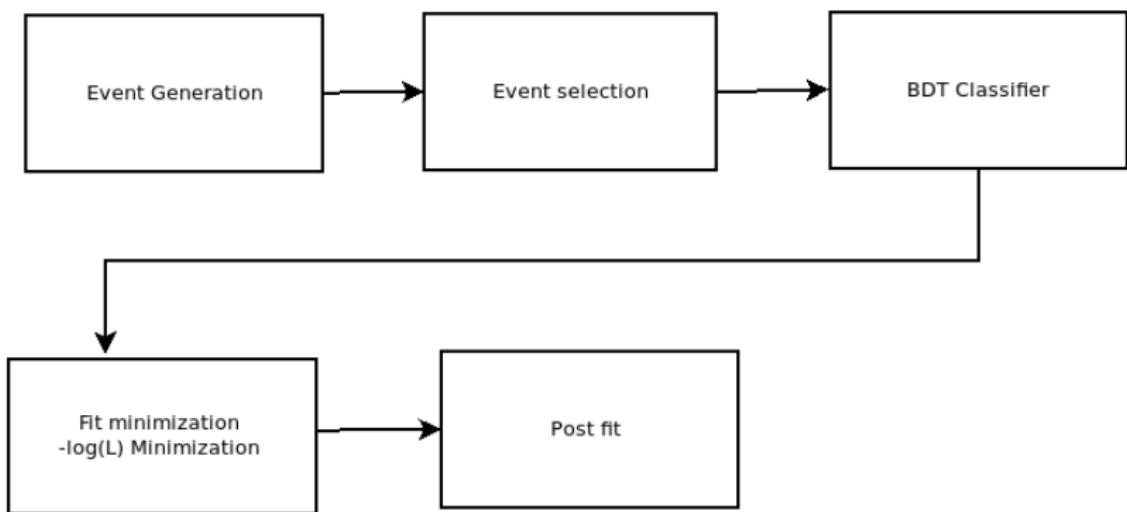

SM signal and backgrounds (Left) and $k_t = -1$ model (Right).

Systematic uncertainties

- The uncertainties on $t\bar{t}W$ and $t\bar{t}Z$ event yields are mainly due to the uncertainties of their production cross sections.
- The uncertainty on WZ background is estimated using real data events in a three lepton control region.
- In the Rare backgrounds, which are not measured, a 50% of uncertainty is assigned.
- The uncertainty on the Fakes background is estimated using real data in a control region, defined by the muon identification criteria.
- For the Higgs processes tH and ttH , the uncertainty are due to the theoretical parameters used in that simulation.

Fitting

Likelihood model

- To estimate the sensibility of the tH signal, we define an Asimov dataset, made by replacing the ensemble of simulated backgrounds and signal by a single one.
- The statistical uncertainty of the Asimov data is calculated as \sqrt{n} , with n the number of events.
- The likelihood function is the product of Poisson probabilities for all bins

$$L(\mu, \alpha) = \prod_{j=1}^N \frac{(\mu s_j + b_j)^{n_j}}{n_j!} e^{-(\mu s_j + b_j)} \prod_{k=1}^M e^{-\frac{\alpha_k^2}{2}} \quad (6)$$

where N is the total number of bins, n_j is the number of events in a bin j , s_j is the number of signal events, μ is a parameter that modifies the signal strength and b_j is the number of background events.

Likelihood model

- b_j is the sum of different background processes k

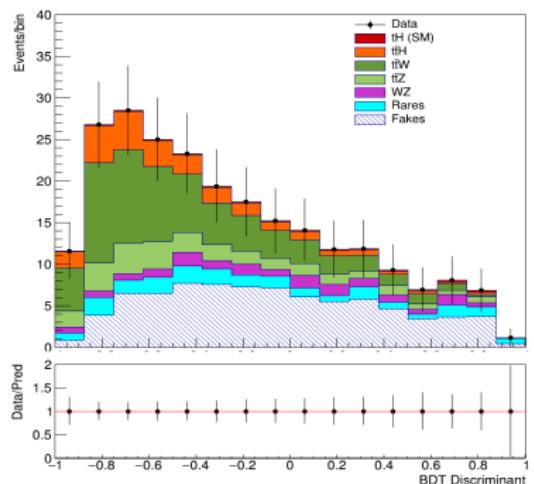

$$b_j = \sum_k^M b_j^k (1 + \alpha_k \sigma_k) \quad (7)$$

α_k is the parameter that modifies the expected background prediction and σ_k is the systematic uncertainty of the associated background. σ_k for the backgrounds are shown in the Table of yields.

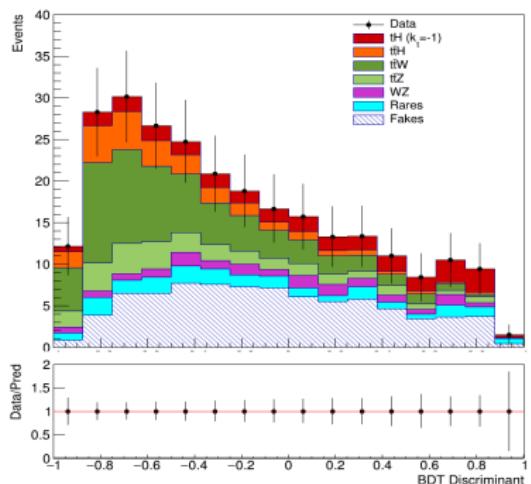

- The fit is applied by minimizing the $-\log L$ (NLL) with respect to the parameter μ and α_k . The minimization is performed by using the package ROOFIT. In the next slides, it shows the results of the model fitting using the Asimov data for the SM and the $k_t = -1$.

Results

Post-fit signal and background yields for tH process in the SM. In the box below each distribution, the ratio of the observed and event yields is shown

Post-fit signal and background yields for tH process in the $k_t = -1$. In the box below each distribution, the ratio of the observed and event yields is shown

Results

Postfit yields for the fit to the Asimov data corresponding to 35.9 fb^{-1} .
The uncertainty given is the combined statistical plus systematic.

Process	SM	$k_t = -1$
$t\bar{t}W$	68 ± 8.9	68 ± 8.9
$t\bar{t}Z$	25.9 ± 3.8	25.9 ± 3.8
WZ	15.1 ± 7.4	15.1 ± 7.4
Rares	20.8 ± 4.8	20.8 ± 4.8
Fakes	80.9 ± 9.0	80.9 ± 8.9
$t\bar{t}H$	24.2 ± 2.0	24.2 ± 2.0
tH	2.1 ± 16.5	26.2 ± 13.1

Prefit uncertainty is statistical only. Postfit uncertainty is statistical + systematic.

Results

Likelihood scan

- Due to the large background, the signal strength for the Asimov data with 35.9 fb^{-1} is consistent with zero. Therefore, we estimate an upper limit on the signal strength at 95% confidence level.
- We can define the likelihood ratio

$$\lambda(\mu, \alpha) = \frac{L(\mu, \alpha)}{L(\hat{\mu}, \hat{\alpha})} \quad (8)$$

Where $\hat{\alpha}$ and $\hat{\mu}$ are the parameters obtained in the previous section which correspond to the minimal of the NLL.

- To determine an upper limit on the strength parameter μ , we use the following statistical test

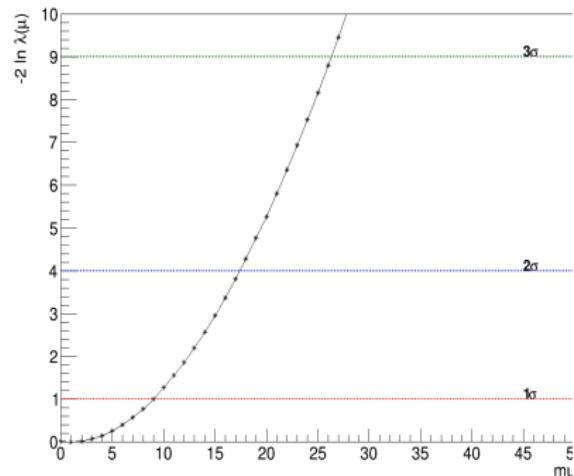

$$q(\mu, \alpha) = -2 \ln \lambda \quad (9)$$

- High values of q represent greater incompatibility between the data and the fit model. q is a random variable with a χ^2 distribution.

Upper limit

Results of μ and upper limits for Asimov extrapolations for SM and $k_t=-1$ models.

Luminosity (fb^{-1})	μ (SM)	μ (SM) upper limit	μ ($k_t=-1$)	μ ($k_t=-1$) upper limit
35.9	1.0 ± 7.7	17	1.0 ± 0.5	2.3
150	1.0 ± 6.7	11	1.0 ± 0.4	1.8
300	1.0 ± 4.3	8.7	1.0 ± 0.3	1.5
3000	1.0 ± 1.7	4.3	1.0 ± 0.1	1.1

Conclusions

- The results of the analysis for the SM case indicates that it is impossible to detect a Higgs boson using same sign dimuon channel in the tH process due to the low number of events and a huge uncertainty.
- For the SM scenario the expected uncertainty even at the largest luminosities is not enough to observe the signal and only an upper limit can be placed.
- For the $k_t = -1$, the uncertainty is low due to higher number of events for tH process and it is possible to detect a Higgs boson, but this model is purely theoretical.
- It requires a new analysis that includes more channels such as three leptons in the final state for improve the sensibility of the signal.
